Dear Retorio Team,

Something cool I built recently: a 16-node LangGraph pipeline that diagnoses a CV against a job posting, rewrites it, then fact-checks every claim against a Chroma-backed evidence store before it's allowed to render — nothing goes out that isn't backed by a real project or repo. It's pinned against a checked-in eval baseline, so a change to the scoring logic shows up as a fixture diff instead of a hope. That's close to your "tested transformation models" ask, just applied to résumés instead of product metrics.

I'm a Data Science MSc student at the University of Europe, looking for a working student role in Munich. Before the MSc I spent 2.5 years as a production engineer at ValueMomentum, where I owned the SQL layer of an insurance data migration: writing and validating the PL/SQL that moved customer, policy, and claims history for a regulated carrier into a new system, then root-causing a data-integrity bug in it afterward. That's the closest match I have to "own the tables, views, and pipelines" in your posting, and it's the part of the job I actually enjoy most.

On the agents and MCP side, alongside the CV pipeline above I built a TypeScript MCP server wrapping the Apify API (15 tools: actor runs, datasets, key-value store) and wired it into Claude Code — that's how I sourced the real job postings I tested the pipeline against. I also shipped a full-stack health app end to end (React, FastAPI, PostgreSQL, live in production), so the "product features, not tickets" side of the role isn't new to me either.

One gap I'll name directly: I haven't used dbt or a dedicated metrics-layer tool. My closest equivalent is the eval-harness discipline above — versioned baselines, tested before a change ships — but it's a different tool, and I'd say so if asked in an interview.

I'm comfortable working onsite in Munich and available now at around 20 hours a week, with room to extend past the five months if it's a good fit on both sides.

Best regards,
Deepak Katukuri
